

Introduction

The present invention relates to an external urinary catheter device for the relief of male urinary incontinence, comprising a contact member which is 5 adapted to be engaged with at least the extreme portion of a penis; an opening formed in a distal end section of the contact member and positioned substantially opposite the urethral orifice in the position of use, and a discharge conduit connected with the opening to 10 provide a sealed urine flow passage extending in a substantial axial direction towards the exterior of the catheter device. The invention also pertains processes for manufacture of an external urinary catheter device for the relief of male urinary incontinence as well as 15 uses of catheters of this kind.

Background art

For the relief of male urinary incontinence external catheters are generally used in the form of 20 condom-like tubular sheaths to be placed externally on penis and having a discharge spout which via a hose is connected with a urine collection bag. Such external catheters are known in numerous designs and in many cases serve as a satisfactory solution of male 25 incontinence problems. However, the complete envelopment of penis may give rise to trouble, partly because the application which is effected by unrolling the catheter requires a certain length of penis, partly in use due to the fact that the envelopment of the full 30 length of penis with the catheter, which is generally fastened adhesively either by means of a separate adhesive strip or by means of an internal adhesive layer, involves strain of the skin of penis. Furthermore, the constant humid environment from the

delivered urine may cause skin problems, such as allergy and maceration and even ulceration.

In recent years various suggestions have been presented in the prior art concerning the use in a 5 urinary catheter of an inner member or a contact member, which in a position of use is positioned between the surface of the corona and the foreskin of the penis.

Thus, from GB-A-2 075 847 an device is known, 10 which comprises a relatively short funnel-like uridom devise to be placed directly against the corona of the penis and to be kept in place under the foreskin. Around a discharge conduit of the device an external sheathing body is fastened in an inverted position to 15 be brought into engagement with the external side of the foreskin after application of the uridom device to maintain the device in place by means of the sandwich position of the foreskin between the contact member and the external sheathing body.

20 Another design is disclosed in GB-A-2 126 483, wherein a more safe retainment of the device in the position of use is implemented by use of a tubular urine ducting device, e.g. of silicone rubber, arranged outside the corona in extension thereof, so that a 25 rather severe extension of the foreskin is required to keep the tubular device in place by arrangement of an adhesive strip or strap member on the external side of the foreskin. Evidently, the rather severe extension of the foreskin required to keep the tubular device in 30 place causes considerable discomfort in use.

In EP-B-0 706 355 and EP-B-0 706 356 external urinary catheters are disclosed in which a safe retainment in the position of use is obtained with considerably less discomfort to the user by means of a 35 short inner contact member designed with improved form

00295760

stability in its distal end part. Aiming at keeping the contact member safely in place under the foreskin the catheter is provided with a separate substantially bowl-shaped outer holder member displaceably 5 surrounding a discharge conduit of the catheter device. The outer holder member is movable between an application position and a position of use.

Urinary catheters are generally connected via a hose to a urine collection bag. The wearer of the 10 urinary catheter suitably places the urine collection bag in a position lower than the position of the urinary catheter to ensure that the urine effectively is drained off by gravity. To allow free movement of the wearer of the urinary catheter the urine collection 15 bag is generally positioned at a part of the leg. Generally, it is preferred to position the urine collection bag at the shin to drain off urine in a standing as well as a sitting position. Furthermore, this position of the urine collection bag provides for 20 the possibility of hiding it behind a trouser leg.

When using the prior art catheters mentioned above the problem arise, following a discharge of urine, that the unbroken column of urine in the hose give rise to a considerable built-up of sub-pressure at 25 the surface of the corona. The wearer of the urinary catheter is subjected to discomfort, especially on extended exposure to the sub-pressure. Suction marks have been observed on the corona due the exposure to sub-pressure. In severe cases, oedema and subsequent 30 infection has been developed.

It has been suggested to overcome this problem by incorporating a vent or a valve in the urine collection bag or the lower part of the hose allowing the surrounding air to communicate with the interior of the 35 catheter-hose-bag environment. Reference is made to

09755288-212990

e.g. US 3,800,857, US 3,835,857, and US 5,622,183. However, the position of a vent or valve in the bag or the lower part of the hose entails the potential risk that urine, when the bag is full or about to be full, 5 will escape the urine collection bag.

Another suggestion is disclosed in US 5,897,540 wherein a slit-shaped opening is provided in a condom-like device for drainage of uncontrolled urine release. The opening is provided for ventilation of the space 10 entrapped between the device and the penis and is placed in the position of use at the main body of the penis well behind the corona. The opening is not provided with a filter or similar means. A further suggestion is disclosed in US 4,656,675, which 15 describes a condom-like device for draining off urine. The device is provided with a filter covering a hole positioned at a point close to the source of urine. The filter is capable of passing air but impervious to liquid at relative low pressures. A major drawback of 20 this suggestion is that the filter is placed at an exposed position. The wearer of the device must be careful since the filter easily can be ripped off by abrasion or accident and the urine will tend to be conveyed through the hole in the device and not as 25 intended through the hose.

It is the object of the present invention to avoid all or some of the above discussed problems and drawbacks of the prior art urinary catheters. Especially, it is an object of the present invention to 30 provide a urinary catheter device having an enhanced reliability and durability due to reduced risk of deterioration.

Description of the invention

The external urinary catheter device of the kind disclosed in the introduction is, according one aspect of the invention, characterized in that an aperture is 5 provided in a distal part of the contact member or in the discharge conduit; a membrane is fastened to the surface surrounding said aperture, the membrane being capable of selectively passing gases but retaining urine; a shield is at least partly 10 protecting the membrane; and at least one vent is arranged for allowing gases to be in substantially unhindered contact with the external surface of the membrane.

The contact member and optionally also further 15 components of the catheter device according to the invention, such as the discharge conduit and the shield, may be made from any material which is suitable for engagement with the sensitive skin of the corona and the foreskin. Suitable materials include 20 thermoplastic elastomeric materials like styrene-butadiene-styrene (SBS), styrene-isoprene-styrene (SIS), styrene-ethylene-butadiene-styrene (SEBS), styrene-ethylene-propylene-styrene (SEPS), polyethers, polyesters, polyamides, polyurethane or any combination 25 thereof; thermoplastic materials such as plasticized polyvinylchloride (PVC), and polyethylene; or curable elastomeric materials like nitril rubber, chloroprene rubber, natural rubber latex, silicone rubber, liquid silicone, polyisoprene or polyurethane. Preferred 30 materials are SEBS and silicone rubber.

The membrane in the device according to the invention allows gas to pass, whereby it is ensured that the amount of urine discharged from a wearer may be drained to a urine collection bag via a hose without 35 leaving a substantial amount of urine in the hose

giving rise to a sub-pressure at the surface of the corona. The term gas as used in the current context means normally ambient air (a gas mixture of predominately nitrogen, oxygen, and water vapour), 5 however, other gases or compositions of gases may come into play. Following a urine discharge the column of urine in the hose will gradually sink to an equilibrium level such that the pressure in the hose above the urine surface essentially corresponds to the pressure 10 of the surrounding environment. A minor column of urine may be present due to a capillary effect and resistance in the membrane, however without entailing a substantial pressure effect on the surface of the corona.

15 The aperture provided in the distal part of the contact member or the discharge conduit may have any suitable dimension. The longest diagonal of the aperture may be larger than the diameter of the discharge conduit. However, to avoid a weakening of the
20 discharge conduit, it is preferred that the aperture has a longest diameter less than the diameter of the discharge conduit. A suitable longest diagonal of the aperture is about 0,25 to 0,75 times the inner diameter of the discharge conduit. Preferably the circumference
25 of the aperture is a circle, however other geometrical shapes might be suitable, such as ovals or polygons. Further suitable shapes are constituted by organic shapes. If desired, more than one aperture may be present in the device. The aperture is preferably
30 positioned at a part of the discharge conduit close to the urethral orifice or the distal part of the contact member to obtain sufficient ventilation. Generally, it is to be avoided to arrange the aperture in a part of the discharge conduit intended to engage with a
35 connector linking the device of the invention with a

卷之三

hose member, to prevent the risk of insufficient gas communication between the inner surface of the membrane and the interior of the discharge conduit. A preferred position of the aperture is in the proximal part of the 5 discharge conduit close to the urethral orifice in a position of use.

A membrane is fastened to the surface surrounding the aperture, the membrane being capable of selectively passing gases but retaining urine. During discharge of 10 urine from the urethral orifice the membrane effectively prevent urine from penetration and thus secure a sealed urine flow passage. Following the discharge of urine gas from the surrounding environment is penetrating the pores of the membrane and 15 consequently, the column of urine in the hose is levelled. The membrane suitably maintain the desired selectivity at the relatively low pressures normally expected during use of the catheter device according to the invention. Normally, the water entry pressure of 20 the membrane should be at least 100 mbar above ambient pressure.

The membrane is generally a thin, hydrophobic, porous sheet having the ability of allowing gas, i.e. air, to penetrate but not urine which is retained. A wide range of materials may be used for the membrane. Preferred materials are generally polymers with a low surface tension to water. Examples of suitable polymers are polyethylene, polypropylene, polyurethane, and polytetrafluoroethylene (PTFE). Membranes of PTFE are commercially available under various trademarks, e.g. Goretex®. A preferred membrane of polyethylene is commercially available under the trademark Tyvek®.

While the membrane in one aspect of the invention is designed to retain urine at least at the relatively low pressures expected during normal use, it may be

desirable, in another aspect of the invention, to use a membrane which at pressures above the level normally expected during use, is adapted to allow the passage of urine to avoid backing up of urine against the penis or 5 ballooning of the foreskin. As an example, a sudden rise in pressure is obtained if the hose is kinked. In accordance with the second aspect of the invention the membrane is adapted to allow the passage of urine at pressures over 80 mbar above ambient pressure, 10 preferably over 100 mbar above ambient pressure.

The fastening of the membrane to the surface surrounding the aperture is normally conducted in order to secure a water-tight attachment of the membrane around the aperture. Any suitable method of fastening 15 may be applied, including adhering, rivetting, partly dissolution by solvents, mechanical stress, or welding. Various suitable welding methods exist e.g. thermal, high frequency, ultrasonic, induction, or laser welding. In one aspect of the invention an adhesive is 20 used for adhering the membrane to the surface surrounding the aperture since this method provides a simple and cost-effective way to obtain an effective attachment of the membrane to the surface surrounding the aperture. In another aspect of the invention a 25 rivet is used to fasten the membrane to the surface surrounding the aperture, whereby the membrane is fixed between the male and the female parts of the rivet to providing an effective mechanical attachment of the membrane to the surface surrounding the aperture.

30 In still another aspect of the invention a fastening of the membrane to the surface of the aperture is obtained by melting the surface surrounding the aperture to an opposite surface of the membrane by welding or exposure to solvents. It is, in general, 35 preferred to use welding, which includes applying an

amount of heat sufficient to melt a part of the plastic material, allowing penetration of the melted plastic material into the pores of the membrane and subsequent allowing solidification of the plastic material. Thus, 5 a simple and reliable way to attach the membrane to the surface around the aperture is obtained. A method especially suitably for attaching the membrane to the surface surrounding the aperture is ultrasonic or thermal welding.

10 In some embodiments of the invention it is
advantageous to depress or sink an area surrounding the
aperture and arrange the membrane in this depression.
In such embodiments a space above the external surface
of the membrane is generally obtained which allow
15 sufficient ventilation of gases to and from the
membrane surface.

In a preferred embodiment of the invention the contact member is integrally connected with the discharge conduit via the opening formed in the distal 20 end section of the contact member. This embodiment makes it possible in a single component of the catheter device to integrate several functions, thus, increasing the industrial processability and securing a sealed urinary flow passage. In some areas of application, it 25 may be useful to connect the discharge conduit to the opening formed in the distal end section of the contact member through a stretchable link to maintain the intimate engagement of the contact member with the penis in a position of use even under tensile load 30 conditions acting on the discharge conduit. The stretchable link may for instance be a bellows-shaped member.

The contact member adapted to be engaged with a penis may be an inner member arrangeable in a position 35 of use between the foreskin and the corona of the

penis, an outer member adapted to be positioned on the external face of a penis to provide a sealed contact, and a combination thereof, i.e. an inner member as well as an outer holder member.

5 In case the contact member is an inner member arrangeable in a position of use between the foreskin and the corona of a penis it may comprise a shoulder-like ledge at a substantially plane abutment face of the inner member around and substantially perpendicular 10 to the discharge conduit to retain the inner member in contact with the corona solely by means of the foreskin contacting the outer side of the contact member. An inner member of this kind is disclosed in EP 706 355 B1, the entire disclosure thereof being incorporated 15 herein by reference.

Another suitable inner member which is arrangeable between the foreskin and the corona of a penis or solely on the corona of a penis e.g. in the absence of foreskin in case of circumcising, comprises 20 a plurality of leaves connected to a housing. The leaves are comprised of a film having an adhesive layer on their interior surface thereof to secure an attachment of the device to the corona of a penis. Preferably, the film as well as the adhesive layer is 25 vapour permeable to increase the comfort of the wearer. An inner member of this kind is disclosed in US 5,263,947 and US 5,263,947, the entire disclosure thereof being incorporated herein by reference.

For fastening the inner member in a position of 30 use, it may be advantageous to provide the catheter device according to the invention with an outer holder member. The outer holder member is preferably formed in a distal end section with an opening for the discharge conduit and arrangeable in said position of use, in a 35 substantially fixed axial position with respect to the .

0925010282962601

discharge conduit for circumferential engagement with the external side of the foreskin.

The outer holder member may be made of any suitable soft elastic, semi-rigid or rigid material 5 such as the plastic materials mentioned above for the contact member or, alternatively, it may be made in the form of a web of textile material like gauze, hydrocolloide skin adhesive covered with a film, or non-textile material. For improved engagement with the 10 external side of the foreskin the inner engagement surface of the outer holder member may be coated with a layer of a skin-friendly adhesive, e.g. a hydrocolloide skin adhesive. Such an adhesive layer may be dimensioned with controlled adhesive properties and/or 15 be applied in various patterns as known in the art to control the adhesive force. By use of an adhesive layer the length of the outer holder member in the position of use may be reduced to cover an even shorter part of the foreskin in order to increase comfort in connection 20 with wear or removal of the catheter device.

The inner member may be permanently connected with a surrounding outer holder member having an opening for the discharge conduit by connection means. Suitably, said connection means is designed also to 25 comprise the shield for the catheter according to the invention. Thus, the shield is preferably an extended part of the distal end section of the outer holder member. The connection means serving the dual purpose of permanently connecting the contact member with the 30 outer holding member and shielding the membrane is in one aspect of the invention an essentially tubular member arranged around and having walls substantially parallel to the axis of the discharge conduit.

The contact member adapted to be in engagement 35 with the penis, may in an aspect of the invention be

SEARCHED
INDEXED
COPIED
FILED

adapted to be positioned on the external face of a penis to providing a sealed contact. To ensure an effective sealing between the contact member and the penis the contact member is suitably of a length 5 covering the extreme portion, e.g. the foreskin or the corona, as well as the main body of the penis. An aperture can suitably be provided in a proximal part of the discharge conduit and covered with a membrane. A shield may be provided over the membrane as a separate 10 or integral tubular member with an internal diameter substantially corresponding to or slightly smaller than the external diameter of the discharge conduit to fix the membrane. A stiffening member may be arranged inside the discharge conduit to provide a suitable 15 abutment for the tubular member.

The urinary catheter of the invention comprises at least one vent which is arranged for allowing the gases, e.g. air, to be in substantially unhindered contact with the external surface of the membrane. The 20 vent may be provided in any suitable way to ensure that the gases virtually unhindered can be conveyed from or to at least a part of the surface of the membrane. Thus, vents may be provided in the shield, the discharge conduit or both. Alternatively, the vent may 25 be one or more hollow fibres or the like provided between the inner face of the shield and the outer surface of the discharge conduit to allow gas communication between the external face of the membrane and the surrounding environment.

30 In an aspect of the invention the vent is a single aperture provided in the shield. The aperture in the shield covers preferably the entire active membrane area to allow sufficient ventilation, however, especially in embodiments where the inner face of the 35 shield is not in direct contact with the membrane, it

TOP SECRET

may be desirable to provide the catheter according to the invention with an aperture smaller than the active membrane area to obtain a extended protection of the membrane.

5 In another aspect of the invention, the shield is
provided with a plurality of apertures for ventilation.
This aspect is of particular interest when a space
above the external surface of the membrane is provided
because the entire membrane area may be active. A space
10 above the external membrane may be provided e.g. by
fastening the membrane with a rivet or by attaching the
membrane in a depression of the external surface of the
discharge conduit. A plurality of relatively small
apertures relative to a single larger aperture is
15 regarded to be more effective for protecting the
membrane since sharp or pointed devices to a larger
extent is prevented from coming into intimate contact
with the membrane from the outside of the catheter
device.

20 A vent passage may also be provided using one or
more tracks for channelling the gases to or from the
external surface of the membrane to the surrounding
environment. In particular, one or more track(s) may be
provided in the inner face of the shield to establish a
25 vent passage from the external surface of the membrane
to the exterior of the catheter device.

In one aspect of the invention a plurality of tracks substantially parallel to the axis of the discharge conduit are formed in the inner face of the shield in a part or the entire circumference thereof establishing a vent passage from the external surface of the membrane to the exterior of the catheter device. The aspect of using tracks in the entire circumference of the inner surface of the shield could be advantageous from a production point of view as the

assembling of the catheter is independent of the relative position of the shield and the membrane due to the rotational symmetry of the shield.

The depression (17) receiving the membrane may be 5 provided with one or more depressed track(s) extending in a distal direction beyond the edge of the shield, said track(s) establishing a vent passage from the external surface of the membrane to the exterior of the catheter device. This alternative is attractive from a 10 production point of view since the mould in which the device is formed, may be designed to provide an impression in the catheter part, said impression having the dual purpose of receiving the membrane and establishing an effective ventilation through the 15 track(s). Moreover, the shield may have a tubular rotational symmetrical shape making it possible to assemble the catheter without observing the relative position of the shield and the membrane.

To obtain a large cross-section of the vent(s) 20 one or more track(s) may be provided in the discharge conduit as well as the inner face of the shield, said tracks in common providing one or more channels for ventilation.

The track(s) provided in the discharge conduit 25 and/or the inner face of the shield may have any suitable shape. Normally, the tracks are parallel to the axis of the discharge conduit to obtain the shortest channel. Other shapes may be considered to obtain specific properties of the catheter. As an 30 example, the track may be provided with one or more bends to trap dust and to avoid penetration of pointed devices. As another example, tracks on the discharge conduit may be thread-like, whereby the gas is conducted around the axis of the discharge conduit.

The invention also pertains to a process for production of an external urinary catheter device for the relief of male urinary incontinence, which comprises the steps of

5 providing a catheter part comprising a contact member which is adapted to be engaged with a penis; an opening formed in a distal end section of the contact member and positioned substantially opposite the urethral orifice in the position of use; and a
10 discharge conduit connected with the opening to provide a sealed urine flow passage extending in a substantial axial direction towards the exterior of the catheter device.

providing an aperture in a distal part of the 15 contact member or in the discharge conduit.

fastening a membrane to the surface surrounding said aperture, the membrane being capable of selectively passing gases but retaining urine,

providing a shield to protect the membrane, and
20 arranging at least one vent for allowing gases to
be in substantially unhindered contact with the
external surface of the membrane.

The catheter part comprising the contact member, opening and discharge conduit may be assembled of 25 individual members or be produced in one piece. It is preferred to produce the catheter part in one piece due to the process economy by integrally connecting the contact member to the discharge conduit via the opening formed in the distal end section of the contact member. 30 The catheter part may suitably be produced by plastic injection moulding using the polymer materials previously mentioned.

The aperture may be provided in any suitably way ensuring that gases substantially unhindered can communicate with the internal face of the membrane. In

case the catheter part is produced in one piece by plastic injection moulding the mould is suitably adapted to provide the aperture during manufacture of the catheter part.

5 The membrane fastened to the surface surrounding the aperture is suitably fastened such that it is secured that a water-proof attachment is obtained. The fastening procedure may be any suitable method securing a water-proof attachment, including adhering, 10 rivetting, partly dissolution by solvents, and welding.

A preferred method of attachment comprise melting the surface surrounding the aperture to an opposite surface of the membrane. A preferred method of fastening the membrane to the surface surrounding the aperture is 15 conducted by welding. Various welding methods are suitable, including ultrasonic, high frequency, induction, laser, and thermal welding. It is in general preferred to conduct the fastening by ultrasonic or thermal welding.

20 In an aspect of the invention according to the above process it pertains to the step of further providing the catheter part with an outer holder member for fastening the contact member in the position of use, wherein the outer holder member is formed in a 25 distal end section with an opening for said discharge conduit and arrangeable in a position of use, in a substantially fixed axial position with respect to the discharge conduit for circumferential engagement with the external side of the foreskin.

30 The invention also provides a dip forming process for manufacture of an external urinary catheter device for the relief of male urinary incontinence, comprising the steps of

35 a) providing a liquid polymer solution or emulsion comprising a polymer and a solvent or a diluent

100000-3839570

in an amount sufficient for permitting dip forming,

b) providing a form having a first part for forming a contact member adapted to engage with a penis,

5 a second part for forming an opening in the distal end section of the contact member and a third part for forming a discharge conduit, the first, second and third part being integrally connected,

10 c) dipping said form in said solution or emulsion,

d) removing the form from the solution or emulsion,

e) allowing the solvent or the diluent to evaporate, and

f) optionally, repeating the steps c), d), and e)

15 until the device has attained the desired wall-thickness, wherein

a membrane, capable of selectively passing gases but retaining urine, is arranged at the part of the form for forming the distal part of the contact member or

20 the third part of the form forming the discharge conduit prior to dipping according to step c) or during evaporation according to step e).

During the manufacture it should be ensured that the polymer film resulting from step e) is prevented

25 from coming into contact with the internal and the external face of the membrane or the polymer film is only releasably attached to the membrane surface to allow the provision of an aperture and a vent on the internal and the external face of the membrane,

30 respectively.

The liquid polymer solution or emulsion for performing the dip forming process according to the invention may comprise any polymer material which is suitable for engagement with the sensitive skin of the

35 penis. Examples of suitable polymers include SBS, SIS,

1234567890

SEBS, natural rubber latex, SEPS, polyisoprene, polychloroprene, nitril rubber, silicone rubber, curable liquid silicone, polyurethane and any combination and quality thereof.

5 In the instance the liquid polymer is a solution, the solvent for dissolving the polymer is suitably an inert solvent of an aromatic or aliphatic nature or a combination thereof, however any solvent able to create a stable solution may be applied. The amount of solvent 10 is appropriately sufficient for obtaining a solution without precipitations of polymer. In general the amount of solvent is higher than the minimum required for obtaining a solution to obtain a viscosity suitable for dip forming. A preferred amount of solvent is from 15 400 to 1200 % by weight, based on the amount of polymer.

When the liquid polymer is an emulsion, the polymer is diluted with a suitable diluent. Preferably, the liquid polymer also contains an emulsifying agent 20 to stabilize the emulsion. A suitable diluent is water. It is generally preferred that the emulsion contains sufficient diluent so as to obtain a viscosity of 100 cp to 1000 cp. The emulsion may optionally comprise a suitable coagulation agent, such as $\text{Ca}(\text{NO}_3)_2$ or CaCl_2 , 25 to obtain an increased wall-thickness. Furthermore, the emulsion may contain a curing agent. The curing agent may e.g. be activated by heat, moisture, ultra violet light, or electron beam. For certain kinds of polymers, e.g silicone, it is possible to prepare a liquid 30 polymer suitable for dip forming without the usage of a diluent.

The form for dipping into the polymer solution or emulsion is appropriately adapted for receiving a membrane in the part of the form for forming the distal 35 part of the contact member and/or in the third part of

1000 999 998 997 996 995 994 993 992 991 990 989 988 987 986 985 984 983 982 981 980 979 978 977 976 975 974 973 972 971 970 969 968 967 966 965 964 963 962 961 960 959 958 957 956 955 954 953 952 951 950 949 948 947 946 945 944 943 942 941 940 939 938 937 936 935 934 933 932 931 930 929 928 927 926 925 924 923 922 921 920 919 918 917 916 915 914 913 912 911 910 909 908 907 906 905 904 903 902 901 900 899 898 897 896 895 894 893 892 891 890 889 888 887 886 885 884 883 882 881 880 879 878 877 876 875 874 873 872 871 870 869 868 867 866 865 864 863 862 861 860 859 858 857 856 855 854 853 852 851 850 849 848 847 846 845 844 843 842 841 840 839 838 837 836 835 834 833 832 831 830 829 828 827 826 825 824 823 822 821 820 819 818 817 816 815 814 813 812 811 810 809 808 807 806 805 804 803 802 801 800 799 798 797 796 795 794 793 792 791 790 789 788 787 786 785 784 783 782 781 780 779 778 777 776 775 774 773 772 771 770 769 768 767 766 765 764 763 762 761 760 759 758 757 756 755 754 753 752 751 750 749 748 747 746 745 744 743 742 741 740 739 738 737 736 735 734 733 732 731 730 729 728 727 726 725 724 723 722 721 720 719 718 717 716 715 714 713 712 711 710 709 708 707 706 705 704 703 702 701 700 699 698 697 696 695 694 693 692 691 690 690 689 688 687 686 685 684 683 682 681 680 680 679 678 677 676 675 674 673 672 671 670 670 669 668 667 666 665 664 663 662 661 660 660 659 658 657 656 655 654 653 652 651 650 650 649 648 647 646 645 644 643 642 641 640 640 639 638 637 636 635 634 633 632 631 630 630 629 628 627 626 625 624 623 622 621 620 620 619 618 617 616 615 614 613 612 611 610 610 609 608 607 606 605 604 603 602 601 600 600 599 598 597 596 595 594 593 592 591 590 590 589 588 587 586 585 584 583 582 581 580 580 579 578 577 576 575 574 573 572 571 570 570 569 568 567 566 565 564 563 562 561 560 560 559 558 557 556 555 554 553 552 551 550 550 549 548 547 546 545 544 543 542 541 540 540 539 538 537 536 535 534 533 532 531 530 530 529 528 527 526 525 524 523 522 521 520 520 519 518 517 516 515 514 513 512 511 510 510 509 508 507 506 505 504 503 502 501 500 500 499 498 497 496 495 494 493 492 491 490 490 489 488 487 486 485 484 483 482 481 480 480 479 478 477 476 475 474 473 472 471 470 470 469 468 467 466 465 464 463 462 461 460 460 459 458 457 456 455 454 453 452 451 450 450 449 448 447 446 445 444 443 442 441 440 440 439 438 437 436 435 434 433 432 431 430 430 429 428 427 426 425 424 423 422 421 420 420 419 418 417 416 415 414 413 412 411 410 410 409 408 407 406 405 404 403 402 401 400 400 399 398 397 396 395 394 393 392 391 390 390 389 388 387 386 385 384 383 382 381 380 380 379 378 377 376 375 374 373 372 371 370 370 369 368 367 366 365 364 363 362 361 360 360 359 358 357 356 355 354 353 352 351 350 350 349 348 347 346 345 344 343 342 341 340 340 339 338 337 336 335 334 333 332 331 330 330 329 328 327 326 325 324 323 322 321 320 320 319 318 317 316 315 314 313 312 311 310 310 309 308 307 306 305 304 303 302 301 300 300 299 298 297 296 295 294 293 292 291 290 290 289 288 287 286 285 284 283 282 281 280 280 279 278 277 276 275 274 273 272 271 270 270 269 268 267 266 265 264 263 262 261 260 260 259 258 257 256 255 254 253 252 251 250 250 249 248 247 246 245 244 243 242 241 240 240 239 238 237 236 235 234 233 232 231 230 230 229 228 227 226 225 224 223 222 221 220 220 219 218 217 216 215 214 213 212 211 210 210 209 208 207 206 205 204 203 202 201 200 200 199 198 197 196 195 194 193 192 191 190 190 189 188 187 186 185 184 183 182 181 180 180 179 178 177 176 175 174 173 172 171 170 170 169 168 167 166 165 164 163 162 161 160 160 159 158 157 156 155 154 153 152 151 150 150 149 148 147 146 145 144 143 142 141 140 140 139 138 137 136 135 134 133 132 131 130 130 129 128 127 126 125 124 123 122 121 120 120 119 118 117 116 115 114 113 112 111 110 110 109 108 107 106 105 104 103 102 101 100 100 99 98 97 96 95 94 93 92 91 90 90 89 88 87 86 85 84 83 82 81 80 80 79 78 77 76 75 74 73 72 71 70 70 69 68 67 66 65 64 63 62 61 60 60 59 58 57 56 55 54 53 52 51 50 50 49 48 47 46 45 44 43 42 41 40 40 39 38 37 36 35 34 33 32 31 30 30 29 28 27 26 25 24 23 22 21 20 20 19 18 17 16 15 14 13 12 11 10 10 9 8 7 6 5 4 3 2 1 0

the form for forming the discharge conduit. The membrane may according to the invention be provided prior to dipping or during the evaporation.

In case the membrane is provided prior to dipping 5 suitable means is provided for securing that the final device is not provided with a polymer film resulting from the evaporation step e). Various means exist, including providing the intended active membrane area with a coating which repels the liquid polymer, using a 10 material for the membrane which in itself repels the polymer solution, covering the intended active membrane area with a removable item, and removing a releaseable attached polymer film from the membrane surface with suitable means.

15 A preferred method of avoiding a polymer film is to press a central part of the membrane against the form from the external side of the membrane by a suitable tool which covers the part of the membrane intended to be the active membrane area. While the 20 central part of the membrane area is pressed against the form, edges and corners of the membrane sheet is embedded in the polymer matrix during the dip forming. It may be advantageous to provide the membrane on a suitable carrier, wherein the carrier material 25 surrounds the active membrane area and is adapted to be able to anchor the membrane in the polymer matrix. Thus, the membrane is shielded as the edges and corners is embedded in the polymer matrix, whereby the risk of deteriorating the membrane during use is reduced. 30 Furthermore, a vent passage is provided by the pressing tool.

It may be preferred to attach the membrane prior 35 the dipping according to step c) to a raised platform to increase the anchoring effect of the material surrounding the active membrane area and to provide for

05070188295765

an aperture having a less tendency to be occluded by the polymer solution during dipping. Preferably, the membrane is kept on the platform during the dip forming procedure by a suitable pressing means, which may allow 5 for the production of a vent passage.

The membrane may also be provided prior to or during evaporation according to step e) or curing if a curing agent is provided in the polymer liquid. Suitably, a sufficient amount of solvent is allowed to 10 evaporate to essentially preserve the dimension stability of an aperture being provided in the polymer film. A membrane sheet comprising an area intended to be active in the final device is arranged such that it covers the aperture and the area of the membrane 15 surrounding the area intended to be active is attached to the area surrounding the aperture. The attachment can be effected in any appropriate way, e.g. by pressing the surrounding area of the membrane into the still fluid polymer matrix or adhering the surrounding area 20 of the membrane to the area surrounding the aperture by any suitable means following evaporation of an essential amount of the solvent. A shield may be provided aiming at protecting the membrane by a repetition of the steps c), d) and e). It must be 25 secured during the repetition that at least one vent is arranged for allowing gases to be in substantially unhindered contact with the external surface of the membrane. The means for providing the vent can be similar to the means for avoiding the polymer film 30 resulting from the evaporation step e), as discussed above. A preferred method is to press a tool against a central part of the external surface of the membrane to protect the intended active membrane area against coming into contact with the polymer solution.

The invention also pertains to a process for manufacture of an external urinary catheter device for the relief of male urinary incontinence, comprising the steps of

5 providing a mould comprising a matrix and a core for plastic injection moulding, wherein the cavity defined by the matrix and the core comprises a first part for forming a contact member adapted to engage with a penis, a second part for forming an opening in 10 the distal end section of the contact member and a third part for forming a discharge conduit, the first, second and third part being integrally connected,

injecting a liquid plastic material into the cavity of the mould,

15 solidification of the liquid plastic material, and recovering the moulded device from the mould, wherein a membrane capable of selectively passing 20 gases but retaining urine is arranged at the part of the cavity for forming the distal part of the contact member or the third part of the cavity for forming the discharge conduit.

The liquid plastic material for the injection moulding process is typically a melted thermoplastic material, which is solid at normal ambient temperatures 25 or a curable liquid polymeric material such as liquid silicone.

During the injection moulding procedure according to the above process it should be ensured that neither 30 the internal face nor the external face of the membrane is occluded by plastic material. In an aspect of the process of the invention the internal face of the membrane is covering an aperture and/or the external face of the membrane is protected with a shield having 35 a vent.

100000-00000000

A vent allowing gases to communicate with the external face of the membrane may be provided by pressing a central part of the membrane against the core by a suitable tool from the matrix side. In 5 addition or alternatively, an aperture allowing urine and gas to communicate with the interior of the membrane surface may be provided by pressing a central part of the membrane against the matrix with a suitable tool from the core side. Suitably, the part of the 10 pressing tool which faces the membrane has an area which may cover a part of the membrane intended to be the active membrane area in the final device. The part of the membrane not pressed with the tool is embedded in the polymer matrix during the plastic injection 15 moulding and provides for an attachment of the membrane to the polymer matrix. To ensure a proper attachment, the membrane may be provided on a carrier having properties which effectively anchor the membrane to the polymer matrix.

20 In may be advantageous to design the mould with a core and/or a matrix which comprise a raised platform as the tool for pressing the membrane against the matrix and/or the core. The embodiment in which the core as well as the matrix comprise a raised platform, 25 the membrane is arranged within the cavity by pressing the two raised platforms against the membrane. This embodiment ensures the production of a device wherein an aperture as well as a vent is provided. Furthermore, the membrane is shielded from deterioration due to the 30 embedment of the edges and corners of the membrane sheet.

Detailed description of the invention

The catheter device shown in Figs. 1, 2, and 3 comprises a contact member 1 which is formed with an opening 5 which in a position of use as shown in Fig. 2 is situated opposite the urethral orifice in the corona 10 of a penis 4. At the opening 5, the distal end section 6 joints discharge conduit 7 by which the catheter may be connected e.g. with a hose member, through which discharges of urine may flow from the 15 contact member into a collection bag not illustrated. Thereby a sealed urine flow passage is provided to extend, from the inner side of the contact member 1 facing the urethral orifice, in a substantially axial direction towards the exterior of the catheter device.

20 As shown in Fig. 2 the contact member 1 is formed to be placed in use under the foreskin 2 of the penis 4 in contact with the corona 3.

In the distal end section 6 around the discharge conduit 7 the contact member 1 is designed with increased form stability so as to form a shoulder-like ledge 13 having e.g. a substantially flat end face so that in use the contact member 1 is retained by the foreskin 2.

To provide an improved sealing effect against the 30 corona 3 the inner side of the contact member 1 is coated with a layer 19 of a skin-friendly adhesive as used for medical devices intended to be in contact with sensitive skin tissue.

In the embodiment shown, the discharge conduit 735 and the contact member 1 are connected with a

surrounding outer holder member 12 having an opening for the discharge conduit 7 via the tubular connection member 20. As shown in Figs 1 and 2, the outer holder member 12 is formed as an invertible substantially 5 bowl-shaped member, which from the inverted application position i Fig. 1 can be brought into the position of use by tilting it around the transition to the connection member 20. An annular applicator not shown on the figures for engagement with the extreme portions 10 of the outer holder member 12 may be used to invert the outer holder member 12 from an application position depicted in Fig. 1 to a position of use depicted in Fig. 2. Such an annular applicator will be effective to facilitate accurate positioning of the contact member 1 15 relative to the corona during application of the catheter device.

The inner engagement surface of the outer holder member 12 is partly or totally coated with a layer 21 20 of a skin-friendly adhesive for improved engagement with the external surface of the foreskin 2. The provision of the adhesive is not compulsory, however, and may be dispensed with, since a sufficient holding force may be obtained by other means, e.g. dimensioning of the outer holder member with a length so as to 25 cover, in the position of use, the entire external side of the foreskin surrounding the corona.

In order to facilitate removal of the catheter device after use the distal end of the tubular connection member 20 is formed with a projecting flap 30 22, which may serve as a grip which can be operated to remove the outer holder member 12 by pulling back the projecting flap 22 in a direction towards the inverted position, from which the holder member was originally applied.

As shown in detail on Fig. 3 an aperture 8 is provided in a proximal part of the discharge conduit 7 relatively close to the urethral orifice in a position of use. A membrane 9 capable of selectively passing 5 gases but retaining urine, is covering the aperture 8 and attached to the area of the discharge conduit surrounding the aperture 8 via an adhesive 23. The membrane 9 is in turn covered with a shield 10, which is a part of the tubular connection member 20, for 10 providing protection of the membrane. A single vent 11 is provided in the shield 10 for allowing gases to be in substantially unhindered contact with the external surface of the membrane. The vent 11 in the shield 10 has a dimension corresponding to the dimension of the 15 aperture 8 allowing the active membrane area virtually unhindered to communicate with the surrounding environment, while preventing the edges and corners of the membrane to be exposed to mechanical wear, thus reducing the risk of deterioration of the membrane.

20 Figs. 4 and 5 show an embodiment of the invention using a rivet 24 to fasten the membrane to an area of the discharge conduit surrounding the aperture. The membrane is fastened to the orifice of the rivet by clamping between the male 25 and the female 26 part of 25 the rivet 24. The male part 25 of the rivet 24 shown on Fig. 5 provides a raised platform for the shield 10, whereby an increased space between the external side of the membrane and the shield is formed. The shield is provided with a plurality of apertures 14 as vents 30 allowing a virtually unimpeded diffusion of gases between the space above the membrane surface and the surrounding environment.

Figs. 6, 7, and 8 show an embodiment of the invention where the membrane is depressed in the 35 surface of the discharge conduit 7 and tracks 18 are

100000-98285767

provided for ventilation. A hand-like depression is cast in the outer face of the discharge conduit, said depression comprising a carpus 27 and three fingers 18 extending in a distal direction. The carpus 27 of the 5 hand-like depression is provided with a membrane 9 attached to the area around the aperture by welding. A tubular shield 10 is covering the carpus 27 and a part of the fingers 18 but not the fingertips. During use of the catheter device of the invention air may be vented 10 through the openings at the fingertips and conducted via the fingers covered by the shield 10 to the external surface of the membrane 9.

Figs. 9, 10, and 11 disclose an embodiment of the invention where the membrane is depressed in the surface of the discharge conduit and tracks in the inner face of the shield provides for the ventilation. A circular depression 28 is formed in the discharge conduit 7 in an area around the circular aperture 8. A membrane 9 is attached to the depressed area around the aperture by welding. A tubular shield 10 is covering the depression and extends over the circumference thereof. Three tracks 29 are provided in the inner face of the shield 10 to establish a vent passage from the external surface of the membrane to the exterior of the catheter device. In operation, air is sucked in at the opening formed by the tracks 29 in the edge of the shield 10. The air is subsequently conducted through the tracks to the external surface of the membrane.

Figs. 12 and 13 show an embodiment of the invention, in which the vent passage is provided by a plurality of tracks formed in the inner face of the shield. The membrane 9 is provided and covers the aperture as explained for the embodiment according to Figs. 1, 2, and 3. A tubular shield 10 is surrounding the part of the discharge conduit harbouring the

aperture covered with the membrane. The edge of the tubular shield extent above the upper edge of the membrane. A plurality of tracks 30 substantially parallel to the axis of the discharge conduit are 5 formed in the inner face of the shield in the entire circumference thereof. In operation, air is sucked in at the openings formed by the tracks 30 in the edge of the shield 10 and subsequently conveyed to the external surface of the membrane. Thus, the tracks 30 10 establishes a vent passage allowing air from the exterior of the catheter to come into contact with the surface of the membrane.

While in the foregoing, embodiments of the invention have been disclosed in considerable detail 15 for purpose of illustration, it will be understood by those skilled in the art that many of these details may be varied without departing from the spirit and scope of the invention.
